

# Alternatives to Venting of Natural Gas – ANG gas capture to reduce emissions

# Categories of emission or venting

---

- **Natural gas emissions to the atmosphere result from several on-shore gas industry processes and operations, but can be categorised by four general types. These are:**
  - **Fugitive emission (unplanned and uncontrolled)**
  - **Process venting (planned, function of system operation)**
  - **Venting from maintenance work (planned and controlled)**
  - **Emergency vents (unplanned but controlled)**

# Natural Gas Venting Reduction

## Reduce Natural Gas Venting

## Approach

By design

- **Don't vent gas in the first instance – design features and processes that prevent venting**
- **Ensure any new equipment installed does not vent gas**

By detection and repair

- **Extend emission and leakage surveys**
- **Take remedial actions to reduce leakage**
- **Develop procedures to keep emissions low through new systems and improved training/awareness**

By reducing losses during operations

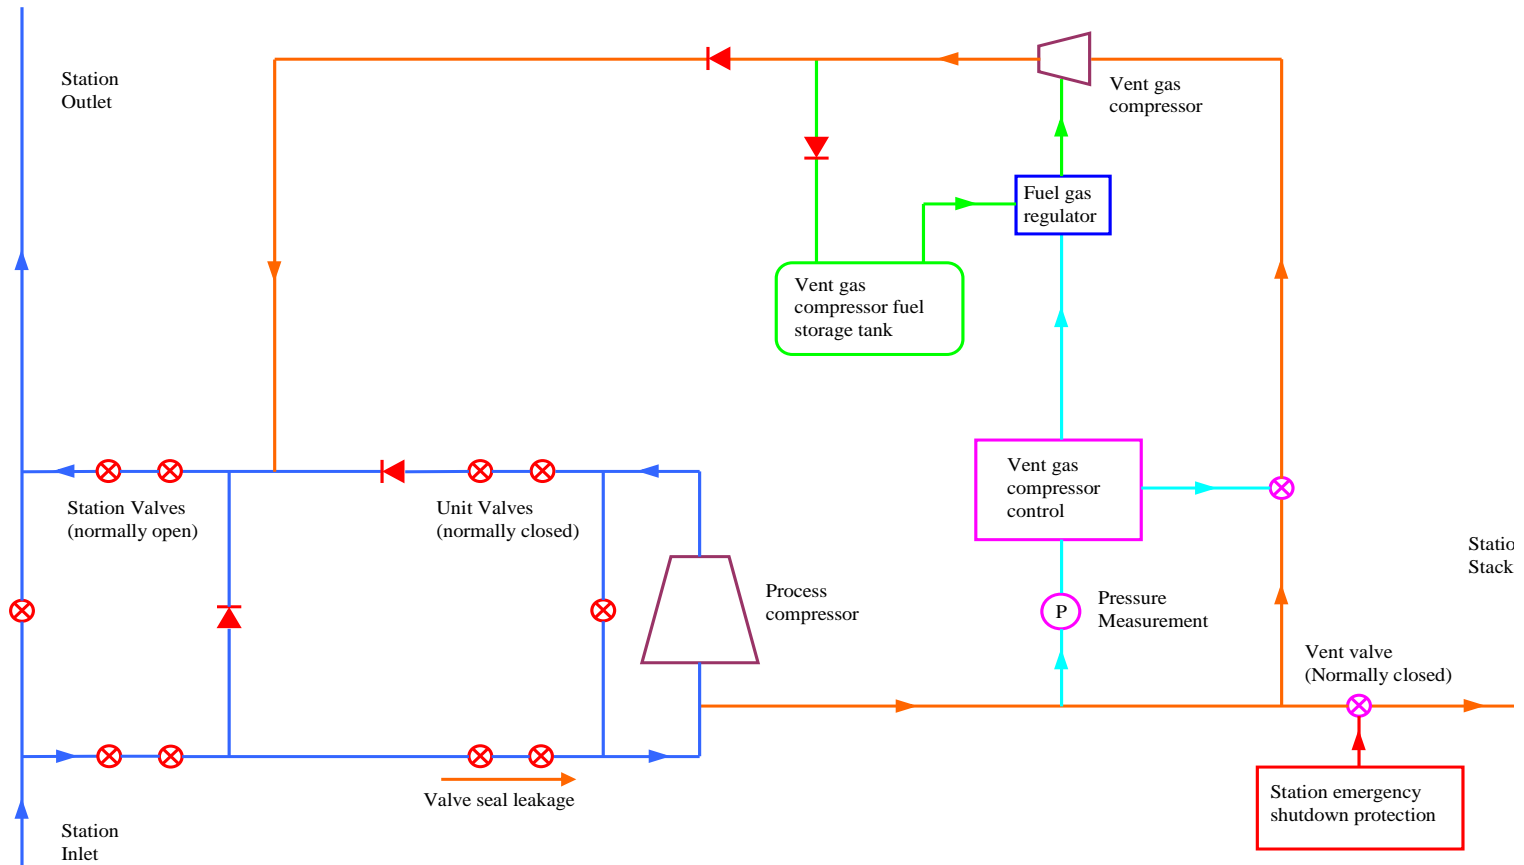

- **Improve operational and/or maintenance practices and procedures**
- **Capture and re-use the vented gas (or flare it)**
- **Gas transfer by recompression**

# Key objectives of this study

---

- To find technological solutions to reduce the gas vented volumes :
  - Prevent the methane emission in the first place (new processes, technologies or equipment)
  - Capture the methane emission (and then use the gas somewhere else or return it to the network)
  - Flare the gas to convert it to CO<sub>2</sub>
- Feasibility Study to evaluate options, develop solutions and focus on cost and environmental benefit view-point. Three aspects highlighted:
  - Recompression – gas transfer from an isolated section to a “live section”
  - Capture the gas that would be vented (using specific technology eg. ANG) then re-use it
  - Flare the gas rather than vent it.
- Main project: **Undertake a series of field trials of selected technologies to raise awareness and provide validation data**

# Concept of gas capture at a Compressor Station

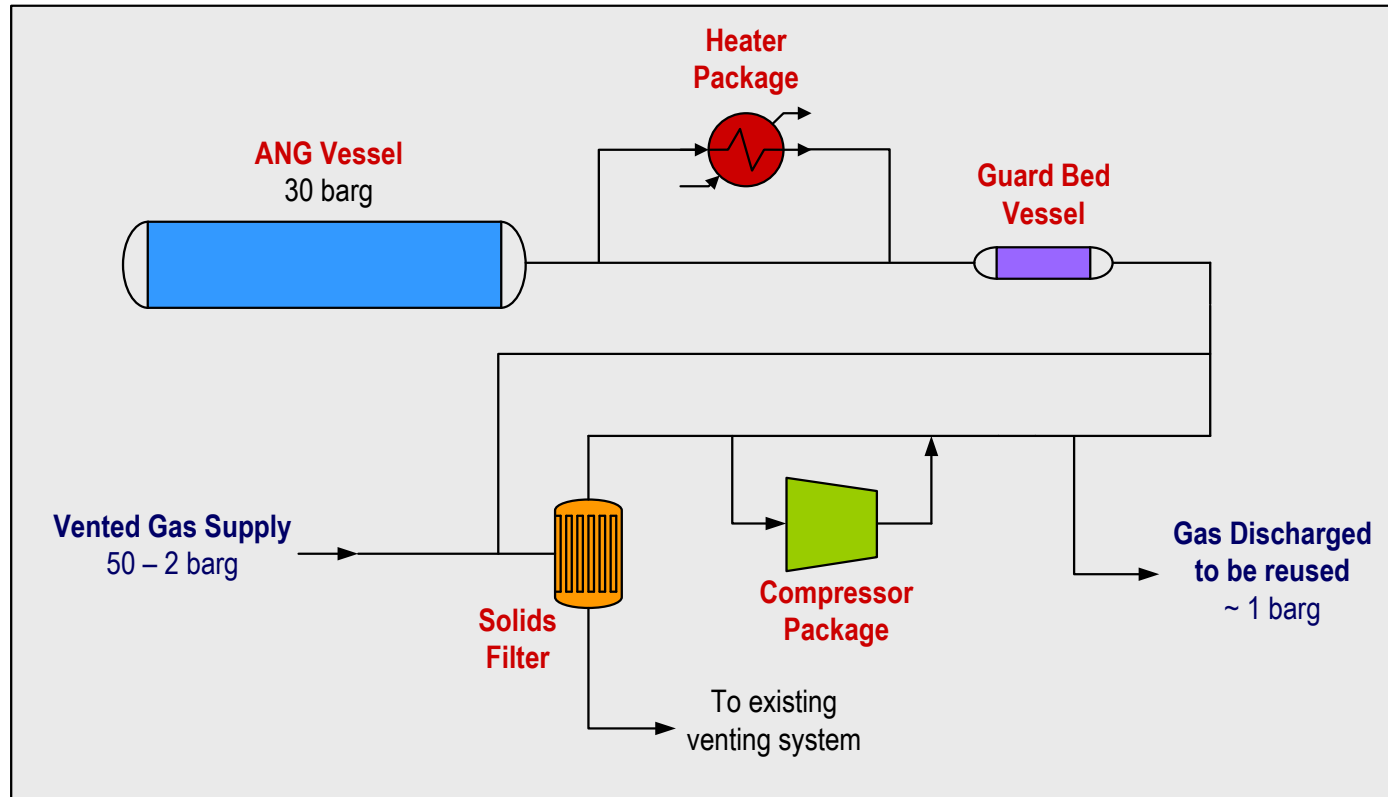

# Introduction to ANG Technology

- **Adsorption of natural gas** onto adsorbent at low or intermediate pressure ranging from 5 to 50 bar.
- Adsorbent has a **high porosity** to achieve maximum storage capacity.
- **Greater energy density** than Compressed Natural Gas (CNG) at same pressure.

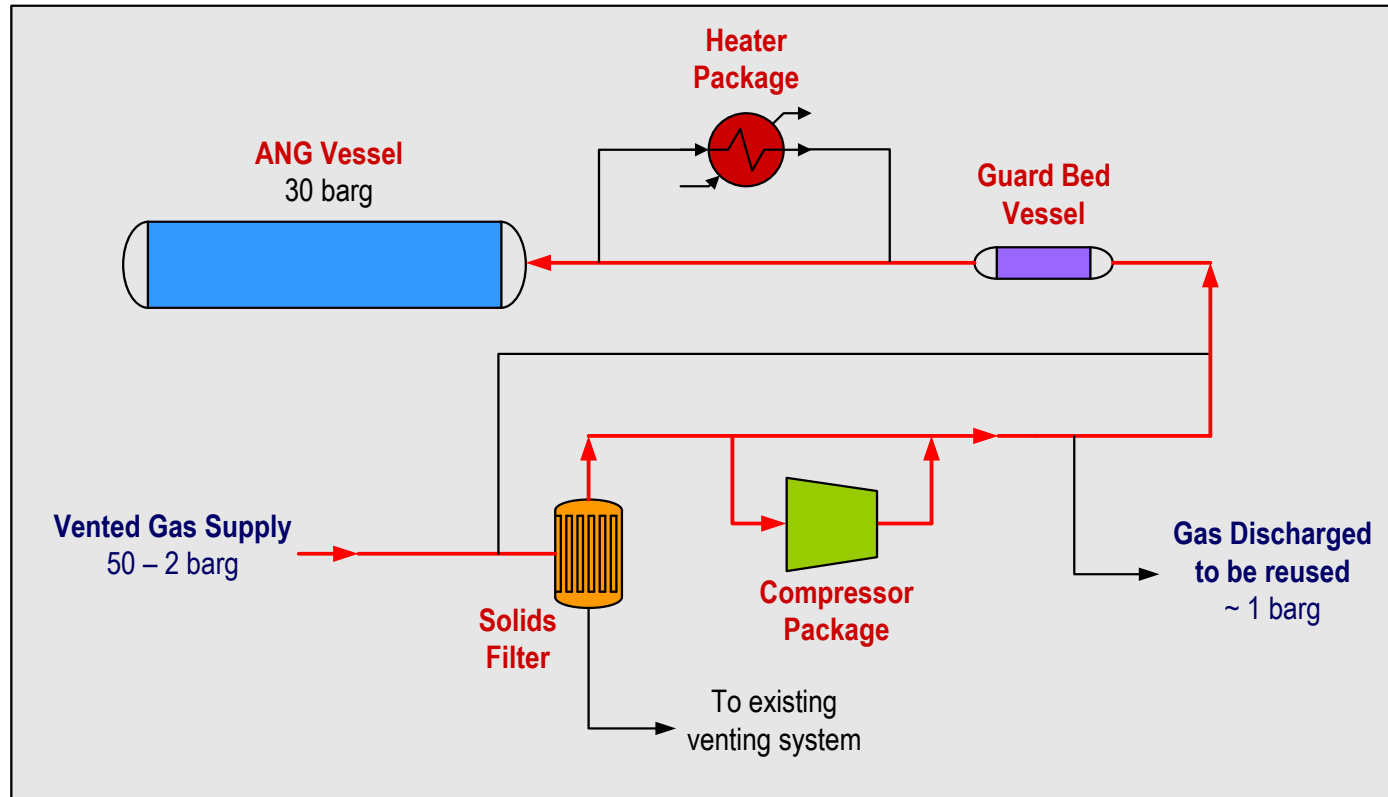

# ANG Process Overview

# ANG Process Overview

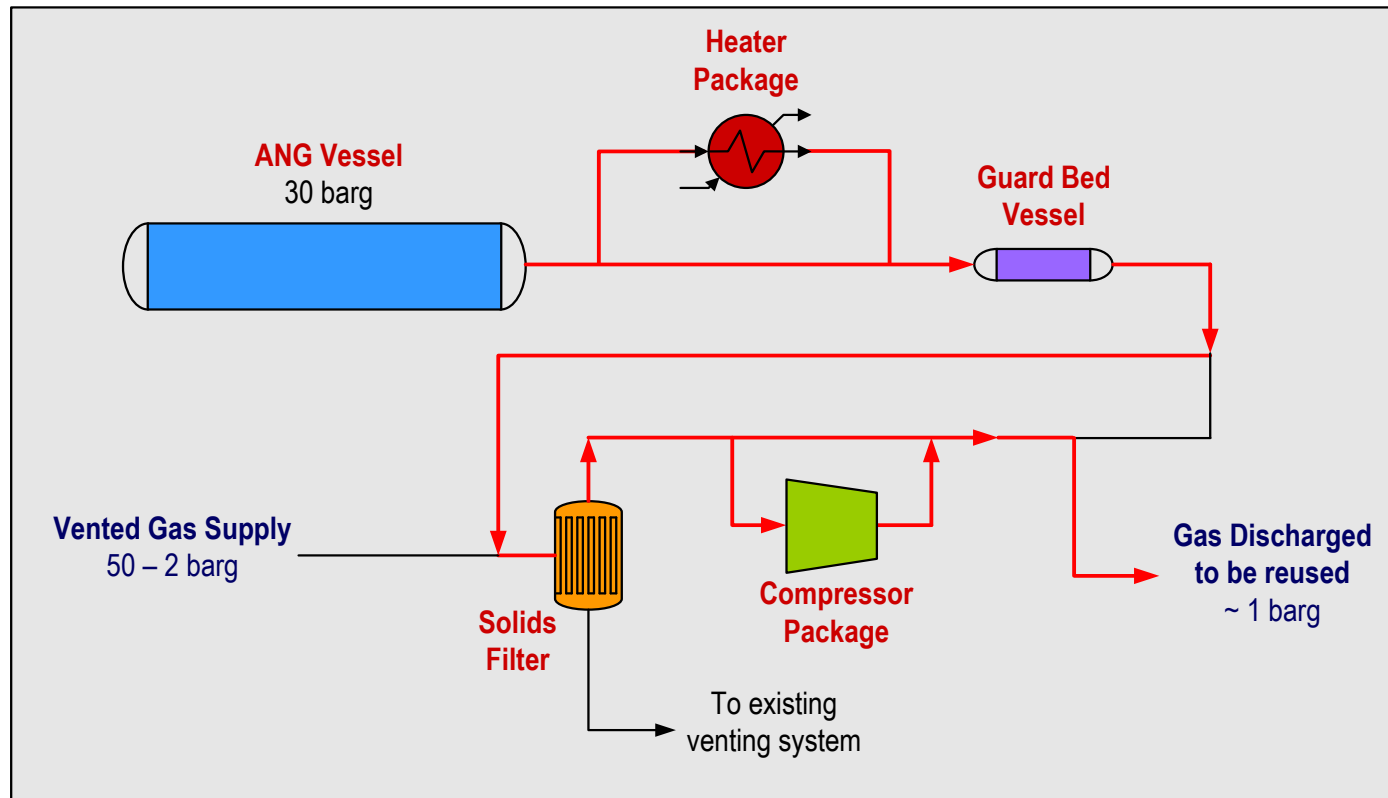

- Charging Phase

# ANG Process Overview

- Discharge Phase

# Layout of Test Facility

- To capture approximately 400 kg of natural gas.
- Footprint of test rig is 14 m x 22 m = Area of 308 m<sup>2</sup>

# ANG Trial Objectives

---

- To evaluate the performance and capabilities of the ANG storage technology and carbon footprint.
  - To replicate **venting scenario** at National Grid Compressor Site
  - To evaluate and verify the **capacity** for the selected installation
  - To optimise the **control of gas quality**
  - To verify the **carbon footprint reduction**
  - To determine the **time taken** to capture and store gas
  - To demonstrate **cyclic operation**

# ANG Vessel Design

## Thermocouple Locations

Metal Framework

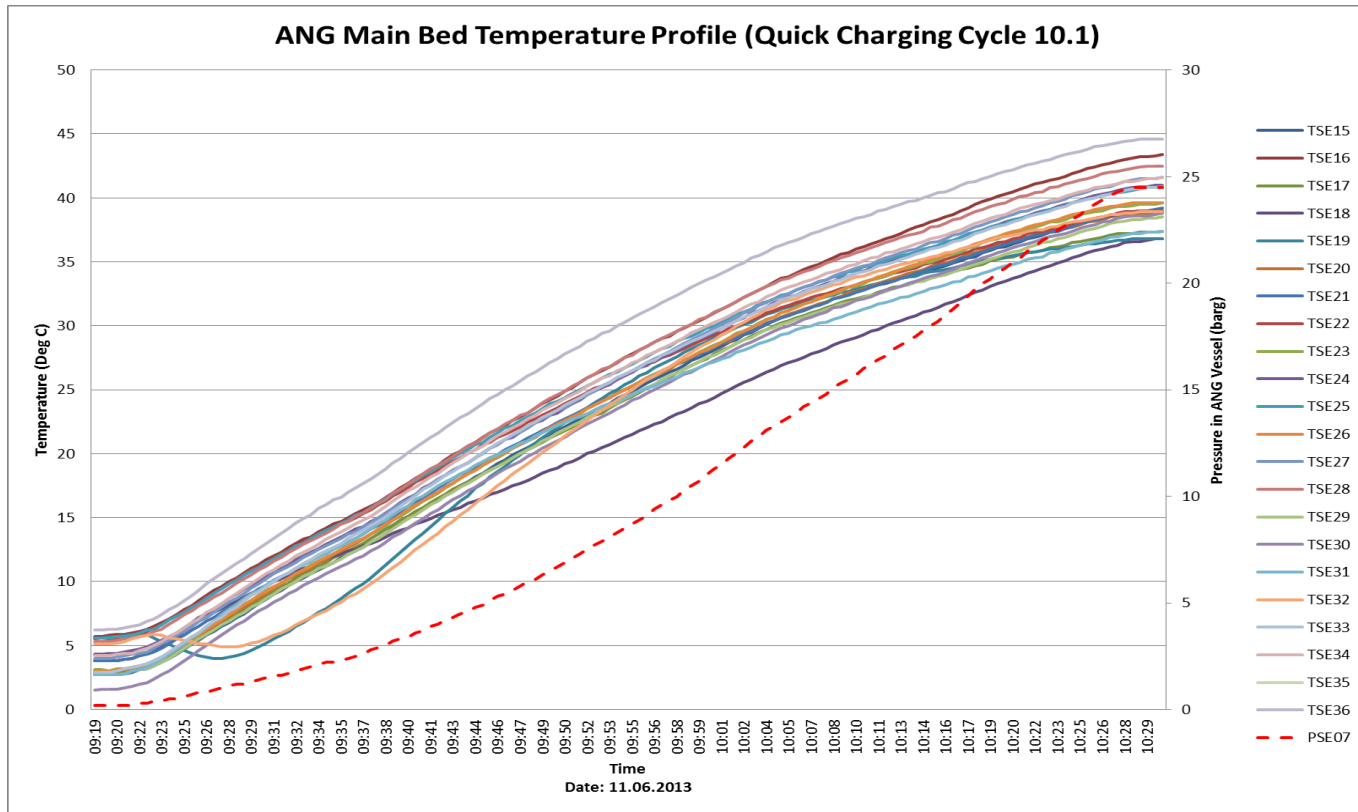

---

# **GAS CAPTURE FIELD TRIAL RESULTS**

# Adsorption Process

- Adsorption phase → Adsorbent bed heats up

# Desorption Process

- Desorption phase → Adsorbent bed cools down

# Guard Bed Temperature Profile

**Guard Bed**

# Storage & Delivered Capacity

- The results show that at full scale and a pressure of 30 barg, ANG provides a 70% increase in working capacity compared to CNG.

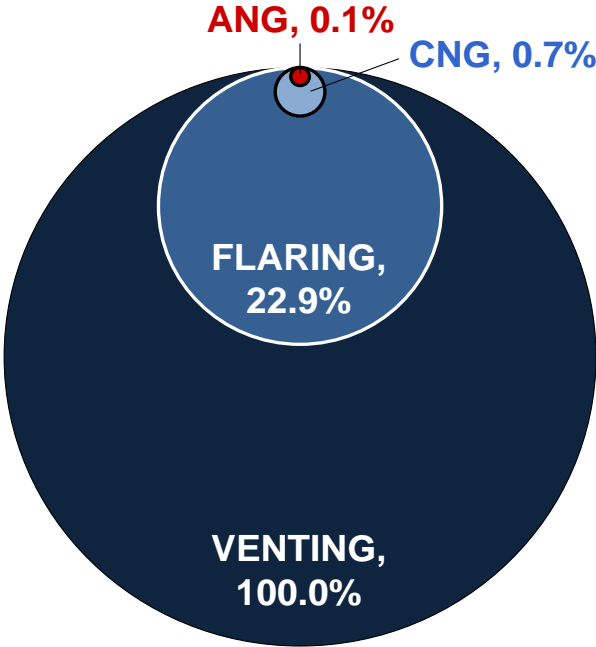

# Gas Quality

- The average WI of the charge and discharge phases were within the range set by GS(M)R.

# Carbon Footprint Reductions

- Figure below shows the comparison of carbon footprint using different technologies as an alternatives to venting.

# Achievements

---

- **“Full” scale demonstration** of ANG technology.
- The trial was successful and met all the objectives.
  - The trial and facility have been designed to mimic the expected venting and capture process at a compressor site.
  - The system installation can capture close to 400 kg of natural gas and showed the benefit of **70% storage enhancement compared to CNG**.
  - For these scenarios, ANG technology gives **the greatest carbon footprint reduction** compared to recompression and flaring.
  - During the discharge phase, the gas delivered meets the **transmission pipeline gas quality specification**.
  - There is **no evidence of carbon performance reduction** from the cyclic operations.
