

## SETTING UP ELECTRONIC DATA BASES OF GLOBAL CO<sub>2</sub> SE- QUESTRATION PROJECTS

V.Yu. Khvostova (Gazprom VNIIGAZ LLC, Russian Federation)

S.A. Khan (Gazprom JSC, Russian Federation)

### Introduction

CO<sub>2</sub> capture is a very important part of the energy strategy of every country. The application of innovative pure technologies in the power industry will reduce carbon dioxide emissions. Setting up long-term underground carbon dioxide reservoirs is considered and implemented as one of promising and widely developing areas. The technology of carbon dioxide capture and sequestration will contribute to the changes of energy policy and reduction of the negative impact of man-caused emissions on the environment. The growth of gaseous industrial emissions and the intensity of their environmental impact have its territory and time scope that does not depend on economy development in Russia. The issue of reducing gaseous emissions can be addressed only on the global level. Therefore, all international efforts were united and as a result several dozens of projects have been developed and successfully implemented for over 15 years. Despite serious disputes about the impact of carbon dioxide on environmental temperature change, global projects are developed and implemented, which is primarily caused by the improvement of the environment condition.

In 2009 the Climate doctrine was adopted in Russia. It was followed by the Comprehensive Plan of Implementation of the Climate Doctrine of the Russian Federation to 2020, which was approved in April 2011. Gazprom and Gazprom VNIIGAZ also take part in a number of initiatives aimed at studying the technology of CO<sub>2</sub> capture and sequestration, which will allow Russia to take part in international projects on capture and long-term storage of gaseous industrial emissions.

### Objectives and methods

The analysis of global projects on CO<sub>2</sub> capture and sequestration will allow to unite them into a data base that can be modified and adjusted depending on the project development. This analysis and data base show the worldwide experience and prospects of CO<sub>2</sub> capture and sequestration projects. It will be an essential document for such major CO<sub>2</sub> organizations as International Energy Agency, Carbon Sequestration Leadership Forum and Global CCS Institute.

To set up a data base of global CO<sub>2</sub> capture and sequestration projects, the analytical method was used. The existing documents on each project were collected, processed, analyzed and generalized and the respective information was systematized. It was a comprehensive study and included the analysis not only of general information, but also geological and hydrochemical data.

### Results

The technology of CO<sub>2</sub> capture and sequestration is an important aspect of addressing the issue of global CO<sub>2</sub> emissions from industrial and energy sources, reduction of the negative impact of carbon dioxide on the environment for the countries with significant CO<sub>2</sub> emissions and suitable for this technology (having underground storages).

In July 2009 the G8 Summit that was held in Aquila, Italia, identified and set criteria for launching 20 CO<sub>2</sub> capture and sequestration projects. Upon agreement with Carbon Sequestration Leadership Forum (CSLF) and Global CCS Institute, International Energy Agency (IEA) later improved and clarified these criteria. These seven criteria are as follows.

1) The project scope should be sufficiently large to demonstrate technical and operational viability of future industrial projects on carbon capture and storage:

- CHP using coal should capture about 1 Mt/year of CO<sub>2</sub>;
- CHP using natural gas and GPP should capture about 0,5 Mt/year of CO<sub>2</sub>.

2) Projects should include the complete integration of CO<sub>2</sub> capture, transmission (if necessary) and storage.

3) In the process of project development the main CO<sub>2</sub> storage facility, its parameters and reasonable transmission routes connecting CO<sub>2</sub> capture site and CO<sub>2</sub> storage facility should be identified.

4) All projects should have an inspection, measurement and control plan. This plan provides the high level of confidence that captured CO<sub>2</sub> will be isolated and reliably stored.

5) CO<sub>2</sub> project development strategies should comprise measures for public involvement and unification of public activity on CO<sub>2</sub> project site.

6) Designed projects should be launched on the full-scale before 2020.

7) Main stages of the project should be worked out; corresponding funding is required for running CO<sub>2</sub> capture and sequestration project. The implementation of the project and its investment plans should demonstrate the public and/or private sector support.

In 2009 270 global carbon capture and storage projects were presented to the public, including:

- 130 planned projects;
- 84 running projects;
- 22 completed projects;
- 21 projects were completed by construction of CO<sub>2</sub> capture facilities;
- 7 cancelled projects due to, first of all, inappropriate choice of the injection location and extremely high cost:

- *Red Rock facility (American Electric Power) USA;*
- *Wolverine CFB plant (Wolverine Power Supply Cooperative) USA;*
- *Lubmin-Griefswald (Dong Energy) Germany;*
- *Halten CO2 Project Draugen-Heidrun/Tjeldbergodden (Shell, Statoil) Norway;*
- *BP Peterhead DF1 (BP) UK;*
- *Huntley project (NRG Energy Inc.) USA;*
- *BP Rio Tinto Kwinana DF3 (BP) Australia;*
- 6 projects are awaiting the decision on their implementation:
  - *Fairview ZeroCarbon Project (CO2CRC, CSIRO) Australia;*
  - *BP Carson DF2 (Hydrogen Energy) USA;*
  - *E.ON Killingholme (E.ON) UK;*
  - *FutureGen-Jewett, FutureGen-Mattoon, FutureGen-Odessa, FutureGen-Tuscola (FutureGen Ind. Al.) USA;*
  - *Monash CTL (Monarsh Energy, Shell, Anglo Coal Australia) Australia;*
  - *Moomba Cooper Basin Carbon Storage Project (Santos) Australia.*

158 projects of 238 are integrated, both running and planned, including CO<sub>2</sub> capture from various sources and sequestration, and 80 projects are large-scale.

However, for the last two years from 2009 to 2011 the number of CO<sub>2</sub> capture and sequestration projects has not increased. Today the total number of CO<sub>2</sub> projects amounts to 328. They comprise:

- 238 active or planned projects;
- 59 cancelled and suspended projects;
- 31 completed projects.

Many countries of the world have programs and major commercial projects on carbon dioxide capture and sequestration technology development:

- CO2 Catch up (Nuon) the Netherlands, 2010-2015;
- NLECI Project (Australian Government) Australia, 2011-2012;
- MGSC Oil-bearing flood 1 and Oil-bearing flood II USA, 2009;
- Nero Zero Emission Coal NZEC (UK&China) China, 2007-2014;
- NZEC Cooperation Action within CCS China – EU/COACH (EU&China), 1st phase, 2007-2014;
- Ocean CO2 sequestration (RITE, NEDO et al.) Japan, 1997-2012;
- ICO2N (ICO2N) Canada, 2012-2025;
- Hypogen/Dynamis (SINTEF Energy Research, Alstom et al.) EU, 2014-16;
- COHYGEN (ENEL, ENEA), Italy, 2009;
- Fenn Big Valley Project (Alberta Science and Research Authority) Canada, 1997;
- Alberta Saline Aquifer Project (ASAP) (EPCOR, Enbridge) Canada, 2010-2015;
- CO2-ECBM (Asia Pacific Partnership: CSIRO-JCOAL) Australia-Japan-China, 2011;
- C6 Resources CCS Project (C6 Resources) USA, 2011.

Figure 1 shows the breakdown of planned and launched global CO<sub>2</sub> capture and sequestration projects by years. Figure 1 shows that the number of CO<sub>2</sub> projects rapidly increased in 2003. For the recent 10 years the increasing number of countries become involved in implementation of such projects, use new CO<sub>2</sub> capture technologies. Many organizations, governmental agencies, academies and institutes carry out R&D works aimed at studying CO<sub>2</sub> impact on the reservoir, well integrity, development of carbon dioxide capture and sequestration technologies, creation of highly efficient transmission methods as well as monitoring during the whole period of project implementation. The attention is paid not only to injection of CO<sub>2</sub>, but also sour gas mixture (CO<sub>2</sub>+H<sub>2</sub>S).

Figure 2 shows the breakdown of CO<sub>2</sub> capture and sequestration projects by countries. Leaders of CO<sub>2</sub> capture and sequestration projects comprise Austria, the UK, Germany, Canada, the Netherlands, the USA. The majority of CO<sub>2</sub> projects are implemented by the USA that is actively involved in CO<sub>2</sub> capture and construction of new CHP or modification of existing ones.

Figure 1 – Breakdown of global carbon capture and storage projects by years

Figure 2 – Breakdown of global carbon capture and storage projects by countries

The analysis resulted in the following quantitative breakdown of projects by countries:

**Europe:**

- Bulgaria 2 projects;
- UK 19 projects;
- Hungary 5 projects;
- Germany 14 projects;
- Greece 2 projects;
- Denmark 3 projects;
- Ireland 1 project;
- Island 1 project;
- Spain 3 projects;
- Italy 7 projects;
- Netherlands 12 projects;
- Norway 10 projects;
- Poland 8 projects;
- Romania 1 project;
- Finland 1 project;
- France 5 projects;
- Check Republic 2 projects;
- Sweden 1 project;
- Estonia 2 projects.

**Asia:**

- Vietnam 1 project;
- India 3 projects;
- China 8 projects;
- Malaysia 2 projects;
- United Arab Emirates 1 project;
- Republic of Korea 4 projects;
- Japan 11 projects.

**Australia:**

- Australia 21 projects.

**Africa:**

- Algeria 2 projects.

**South America:**

- Argentine 1 project;
- Brazil 6 projects;
- Venezuela 1 project.

**North America:**

- Canada 21 projects;
- USA 94 projects.

All projects were analyzed by the following criteria:

- carbon dioxide source;
- storage type.

Sources of carbon dioxide emissions can be classified as follows:

- Industrial sector (mineral fertilizers production plants, steel works, alumina and cement plants, ammonia production plants, LNG plants, organic reagent production plants);
- Heat and power stations using the technology of CO<sub>2</sub> capture after fuel combustion (coal, gas);
- Heat and power stations using the technology of CO<sub>2</sub> capture before fuel combustion;
- Heat and power stations using the technology of CO<sub>2</sub> capture with oxygen fuel combustion.

Moreover, carbon dioxide is captured at gas processing plants and oil refineries or directly on fields where gas or oil with increased carbon dioxide content is produced. Carbon dioxide is separated from the main fluid and injected to under- or overlying formations.

As for the storage type, projects are divided as follows:

- the use of CO<sub>2</sub> for enhancing oil and gas recovery and coal methane production followed by its sequestration in the formation;
- the use of CO<sub>2</sub> for manufacturing a new product used in the commercial sector;
- sequestration in geological formations: depleted gas or oil fields; sandstone, carbonate or saline formation; basalt.

Figures 3 - 4 show the projects breakdown by carbon dioxide emission source and storage type.

Figure 3 – Breakdown of carbon capture and storage projects by CO<sub>2</sub> emission sources

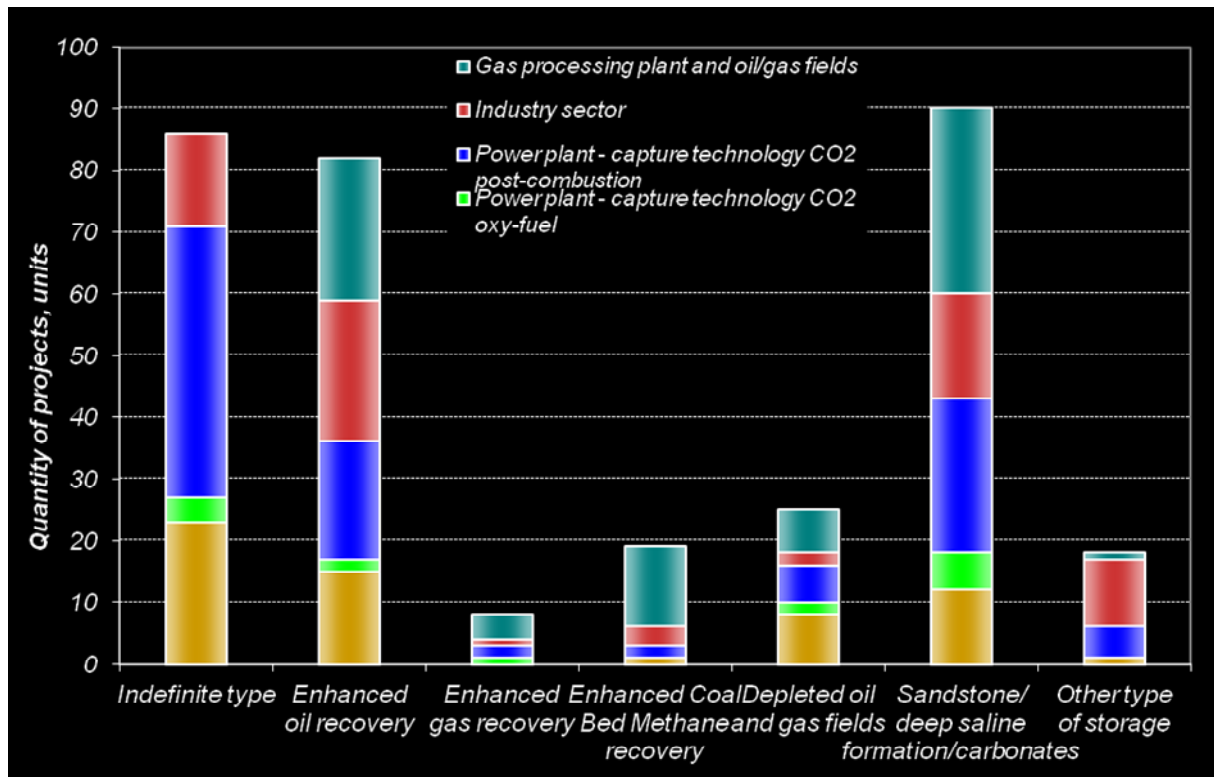

Figure 4 – Breakdown of carbon capture and storage projects by storage type

In the USA the main CO<sub>2</sub> emission source is CHP using the technology of CO<sub>2</sub> capture before fuel combustion, the so called integrated gasification combined cycle (IGCC). In case of other countries the main CO<sub>2</sub> emission source is CHP using the technology of CO<sub>2</sub> capture after main fuel combustion.

Table 1-2 shows examples of global projects breakdown by emission capture source and CO<sub>2</sub> storage/use type.

Table 1 – Global carbon dioxide capture and storage projects

Storage type / Capture type	Storage type is not determined	Coal methane production increase	Oil recovery improvement	Gas recovery improvement	Depleted oil / gas field	Sandstone / carbonate formation / aquifer	Basalt / other
Power plant- Coal post-combustion capture	CHP 480 MW 2,9 Mt/year Siekierki ( <b>Vattenfall</b> ) Poland, 2016	CHP 1200 MW from 2,8 to 5 Mt/year Cockenzie ( <b>Scot. Power, Alstom</b> ) UK, 2012-2014	2 CHP 600 MW 3 - 4 Mt/year Harbin power plant-Daqing Oil Field Project и RITE ( <b>CNPC, Toyota</b> ) China, 2009	CHP 250 MW 1,8 Mt/year Janschwalde ( <b>Vattenfall</b> ) Germany, 2015	CHP 400 MW 0,008 Mt/year Esbjerg Power Station-CASTOR ( <b>EL-SAM-Elsam Power</b> ) Denmark, 2008	CHP 50 MW (total 419 MW) 0,003 Mt to sandstone + 0,01 Mt to carbonate formation Appalachian Basin-ECO2 R.E. Setting up a data base requires not only the general information on the capture project:

- country, location;
- company in charge;
- project cost;
- emission source;
- CHP or plant capacity;
- initial feedstock;
- capture type;
- capture technology;
- transmission to the injection location;
- distance from the source to the injection location;
- storage type;
- volume of injected carbon dioxide;
- date of project launch and completion;-
- project status;
- project type,

But also information on geology and hydro-geology of the formation where the carbon dioxide (or gas mixture) will be stored:

- temperature, pressure;
- formation depth, thickness (general and effective);
- formation mineralogy;
- porosity, permeability (minimum, maximum, average);
- cap lithology, thickness;
- mineralization, saturation and pH of formation water;
- monitoring types.

Geological properties determine the criteria for the selection of reservoirs for long-term and safe storage of carbon dioxide.

Tables 3 – 5 provide examples of general, geological and hydro-geological information on CO<sub>2</sub> projects from the data base on global projects.

Table 3 – General data on global CO<sub>2</sub> projects

The analysis of pressure and temperature properties of projects shows that CO<sub>2</sub> is in liquid or supercritical state. Depth of formations designed for CO<sub>2</sub> sequestration and use varies from 600 to 4500 m. Studies of carbon dioxide long-term storage in underground storages shows the level of efficiency, safety and cost of this method. Carbon dioxide long-term underground storages are considered and constructed as one of promising and actively developing areas.

Works performed in this area and project implementation will in future result in the development of legislative documents regulating emission reduction for a specific region or area using new technologies of industrious gaseous emissions capture and treatment, selection of geological sites for carbon dioxide injection for the purpose of long-term and safe storage.

### Summary

Several countries have started to assess and document (develop a regulatory base) potential and efficient locations for CO<sub>2</sub> sequestration. It is very important but even more important is improving the assessment and identifying all options of CO<sub>2</sub> storages.

The achievement of significant national and international GHG emission stabilization targets will require international cooperation on CO<sub>2</sub> capture and sequestration.

The number of CO<sub>2</sub> projects grows all over the world and new projects appear every day. Many countries have largely invested into CO<sub>2</sub> project studies, development and initial construction, including assessment of potential CO<sub>2</sub> storages. This analysis is a review of CO<sub>2</sub> projects developed and implemented worldwide. Project information is often updated, including legislative regulation, R&D, comprehensive geological and geochemical analysis of formation, dates of project launch, etc.

First of all, project implementation requires identification of connection between CO<sub>2</sub> emission source and injection location. All projects include thorough analysis of potential locations for CO<sub>2</sub> storages, large scope of experiments, studies and calculations of the mechanism of CO<sub>2</sub> capture in a geological structure, physical and chemical processes in the reservoir and risk assessment. The final stage of the project is development of CO<sub>2</sub> transmission infrastructure. The experience obtained by carrying out numerous CO<sub>2</sub> projects and studies will allow to run such a project in Russia and take part in international projects. Today the Russian Federation is involved in development of collective measures of the global community aimed at mitigation of man-caused climatic impact and assists developing countries in implementation of measures aimed at adjustment and mitigation of the negative impact of climate change together with other CO<sub>2</sub> project countries.

Thus, the analytical material gathered and systematized for all global CO<sub>2</sub> projects is an analytical document that can be the basis for rational and efficient selection of potential locations for CO<sub>2</sub> long-term storages and implementation of promising, advanced and safe for subsurface CO<sub>2</sub> capture, transmission, injection and storage technologies.
